## PC Algorithm

## Sparse Models

## Neural Networks

Directed edges:  $A$  causes  $B$ .

Undirected edges:  $A$  and  $B$  are correlated.

Graphical models are defined by a collection of random variables

e.g.  $X = (X_A, X_B, X_C, X_D)$

and a graph  $G = (V, E)$  describing the relationship between the variables.

	Discrete	Gaussian
Directed Acyclic Graphs	Also known as Bayesian networks.	
Undirected Graphs	Also known as Markov random fields.	

# Directed Graphical Models

Sparse Models

Neural Networks

Real log canonical thresholds also allow us to approximate the volume of small tubular neighborhoods of varieties. Such problems occur frequently in error estimation and convergence analysis.

Tubes  $|f(x, y)| \leq t$  for various polynomials in two variables.

# Partial Correlation Algorithm

Graphical Models

Tree Cumulants

PC Algorithm

• Tube Volumes

• **Partial Correlations**

• Faithfulness

Sparse Models

Neural Networks

## Partial Correlations.

Gaussian model with variables  $V$ , concentration matrix  $K = \Sigma^{-1}$ .  
Given  $i, j \in V$  and  $S \subset V \setminus \{i, j\}$ , let  $R = V \setminus (S \cup \{i, j\})$ .

$$\text{corr}_{i,j|S} = \frac{\det(K_{iR,jR})}{\sqrt{\det(K_{iR,iR}) \cdot \det(K_{jR,jR})}}$$

The partial correlation (PC) algorithm constructs directed Gaussian graphical models by inferring conditional independence statements  $i \perp\!\!\!\perp j \mid S$  from the data.

1. Fix a small tolerance  $t > 0$ .
2. Start with a complete graph  $G$ .
3. Run through all triples  $(i, j, S)$ ,  $i, j \notin S$ , systematically.
4. For each  $(i, j, S)$ , compute the partial correlation  $\text{corr}_{i,j|S}$ .
5. If  $\text{corr}_{i,j|S} \leq t$ , then remove edge  $(i, j)$  from graph  $G$ .

# Faithfulness

Graphical Models

Tree Cumulants

PC Algorithm

- Tube Volumes
- Partial Correlations
- **Faithfulness**

Sparse Models

Neural Networks

- A distribution  $p(\cdot|\omega)$  is  **$t$ -strong-faithful** to a graph  $G$  if

$$|\text{corr}_{i,j|S}(\omega)| \leq t \Leftrightarrow i \text{ is } d\text{-separated from } j \text{ given } S.$$

Otherwise, it is **unfaithful**.

- Using singular learning theory, we can approximate the volume of unfaithful parameters as  $t$  goes to zero.

$$\int_{|f(\omega)| \leq t} d\omega \approx Ct^\lambda (-\log t)^{\theta-1}$$

Here  $(\lambda, \theta)$  is the learning coefficient of  $f(\omega) = \text{corr}_{i,j|S}(\omega)$ .  
Determines performance of the PC algorithm for large samples.

- e.g.  $(\lambda, \theta) = \begin{cases} (1, 1) & \text{for all star trees,} \\ (1, p-1) & \text{for a chain with } p \text{ nodes.} \end{cases}$

# Curse of Singularities

Graphical Models

Tree Cumulants

PC Algorithm

Sparse Models

- Big Data
- **Curse of Singularities**
- Singular Model
- Learning Coefficients
- Computation

Neural Networks

- Approximation of high dimensional integrals is difficult because of the curse of dimensionality singularities.

For smooth models, Laplace approximation works well even if parameter space  $\mathbb{R}^d$  has high dimension.

- But many models in machine learning are singular, e.g. mixtures, neural networks, hidden variables.
- Important to analyze asymptotics of integrals with singularities.

# Learning a Singular Model

Graphical Models

Tree Cumulants

PC Algorithm

Sparse Models

• Big Data

• Curse of Singularities

• **Singular Model**

• Learning Coefficients

• Computation

Neural Networks

$$X \sim \mathcal{N}(\omega^2, 1), \quad Y \sim \mathcal{N}(\omega^3, 1)$$

$$\text{data } (X_i, Y_i), i = 1 \dots N$$

$$\text{parameter } \omega \in \mathbb{R}, \text{ mean } (\bar{X}, \bar{Y})$$

- MLE:  $\operatorname{argmin}_{\omega} |\omega^2 - \bar{X}|^2 + |\omega^3 - \bar{Y}|^2$   
BIC performs poorly when MLE is close to 0.

- Recall that the likelihood integral is

$$Z_N = \frac{1}{2\pi} \int_{\mathbb{R}} \exp\left(-\frac{1}{2} \sum_{i=1}^N |\omega^2 - X_i|^2 + |\omega^3 - Y_i|^2\right) d\omega$$

- If true distribution is  $X \sim \mathcal{N}(u^2, 1), Y \sim \mathcal{N}(u^3, 1)$ , then

$$-\log Z_N(u) \approx \frac{1}{2} \sum_{i=1}^N (u^2 - X_i)^2 + (u^3 - Y_i)^2 + \pi(u) + O_p(1)$$

where  $\pi(u) = \frac{1}{4} \log N$  if  $u = 0$ ; otherwise  $\pi(u) = \frac{1}{2} \log N$ .

# Learning Coefficients

Graphical Models

Tree Cumulants

PC Algorithm

Sparse Models

- Big Data
- Curse of Singularities
- Singular Model
- Learning Coefficients
- Computation

Neural Networks

- Given  $u \in \Omega$ , there exist learning coefficients  $(\lambda_u, \theta_u)$  such that for all sufficiently small nbhds  $\Omega_u$  of  $u$ ,

$$\int_{\Omega_u} e^{-Nf(\omega)} \varphi(\omega) d\omega \approx CN^{-\lambda_u} (\log N)^{\theta_u - 1}.$$

- Sparsity penalty for MLE: Given the log likelihood

$$\ell(u) = -\sum_{i=1}^N \log p(X_i|u),$$

for large samples we have the asymptotic approximation

$$-\log Z(u) \approx \ell(u) + \pi(u) + O_p(1)$$

where  $\pi(u) = \lambda_u \log N - (\theta_u - 1) \log \log N$ .

- To find the model  $\mathcal{M}_u$  that minimizes  $Z(u)$ , we compute

$$\operatorname{argmin}_{u \in \Omega} \ell(u) + \pi(u).$$

- This is a generalization of the BIC to singular models.

Sparse Models

Neural Networks

● Motivation

● Boltzmann Machines

● Sensor Networks

Neural networks are highly singular models inspired by biology.

The lack of success forced researchers to abandon these models in the 70's and 80's. But the introduction of multiple layers and nonlinear sparse methods turned the tide. Computationally fast.

Singular learning tells us that proper learning requires sparsity.
